Application Performance Measurement MIB

Status of this Memo

This document specifies an Internet standards track protocol for the Internet community, and requests discussion and suggestions for improvements. Please refer to the current edition of the "Internet Official Protocol Standards" (STD 1) for the standardization state and status of this protocol. Distribution of this memo is unlimited.

Abstract

This memo defines a portion of the Management Information Base (MIB) for use with network management protocols in TCP/IP-based internets. In particular, it defines objects for measuring the application performance as experienced by end-users.

1. The Internet-Standard Management Framework

For a detailed overview of the documents that describe the current Internet-Standard Management Framework, please refer to section 7 of RFC 3410 [8].

Managed objects are accessed via a virtual information store, termed the Management Information Base or MIB. MIB objects are generally accessed through the Simple Network Management Protocol (SNMP). Objects in the MIB are defined using the mechanisms defined in the Structure of Management Information (SMI). This memo specifies a MIB module that is compliant to the SMIv2, which is described in STD 58, RFC 2578 [1], STD 58, RFC 2579 [2] and STD 58, RFC 2580 [3].

2. Overview

This document continues the architecture created in the RMON MIB [7] by providing analysis of application performance as experienced by end-users.

Application performance measurement measures the quality of service delivered to end-users by applications. With this perspective, a true end-to-end view of the IT infrastructure results, combining the performance of the application, desktop, network, and server, as well as any positive or negative interactions between these components.

Despite all the technically sophisticated ways in which networking and system resources can be measured, human end-users perceive only two things about an application: availability and responsiveness.

Availability - The percentage of the time that the application is ready to give a user service.

Responsiveness - The speed at which the application delivers the requested service.

A transaction is an action initiated by a user that starts and completes a distributed processing function. A transaction begins when a user initiates a request for service (i.e., pushing a submit button) and ends when the work is completed (i.e., information is provided or a confirmation is delivered). A transaction is the fundamental item measured by the APM MIB.

A failed transaction is a transaction that fails to provide the service requested by the end user, regardless of whether it is due to a processing failure or transport failure.

An application protocol (e.g., POP3) may implement different commands or application "verbs" (e.g., POP3 Login and POP3 Retrieval). It will often be interesting to monitor these verbs separately because:

- The verbs may have widely differing performance characteristics (in fact some may be response time oriented while others are throughput oriented)
- 2) The verbs have varying business significance
- 3) It provides more granularity of exactly what might be performing poorly

This MIB Module allows the measurement of a parent application, its component verbs, or both. If monitoring both, one can watch the top-level application and then drill down to the verbs when trouble is spotted to learn which subcomponents are in trouble. Each application verb is registered separately in the Protocol Directory [5] [6] as a child of its parent application.

Application protocols implement one of three different types of transactions: transaction-oriented, throughput-oriented, or streaming-oriented. While the availability metric is the same for all three types, the responsiveness metric varies:

Transaction-Oriented: These transactions have a fairly constant workload to perform for all transactions. In particular, to the degree that the workload may vary, it doesn't vary based on the amount of data to be transferred but based on the parameters of the transaction. The responsiveness metric for transaction-oriented applications is application response time, the elapsed time between the user's request for service (e.g., pushing the submit button) and the completion of the request (e.g., displaying the results) and is measured in milliseconds. This is commonly referred to as end-user response time.

Throughput-Oriented: These transactions have widely varying workloads based on the amount of data requested. The responsiveness metric for throughput-oriented applications is kilobits per second.

Streaming-Oriented: These transactions deliver data at a constant metered rate of speed regardless of excess capacity in the networking and computing infrastructure. However, when the infrastructures cannot deliver data at this speed, interruption of service or degradation of service can result. The responsiveness

Waldbusser Standards Track [Page 3]

metric for streaming-oriented applications is the signal quality ratio of time that the service is degraded or interrupted to the total service time. This metric is measured in parts per million.

2.1. Report Aggregation

This MIB Module provides functions to aggregate measurements into higher level summaries.

Every transaction is identified by its application, server, and client and has an availability measure as well as a responsiveness measure. The appropriate responsiveness measure is context-sensitive depending on whether the application is transaction-oriented, throughput-oriented, or streaming- oriented. For example, in a 5 minute period several transactions might be recorded:

Application	Client	Server	Successful	Responsiveness
HTTP	Jim	Sales	1	6 sec.
SAP/R3	Jane	Finance	1	17 sec.
HTTP	Joe	HR	0	_
FTP	Jim	FTP	1	212 Kbps
HTTP	Joe	HR	1	25 sec.
RealVideo	Joe	Videoconf	1	100.0%
HTTP	Jane	HR	1	5 sec.

These transactions can be aggregated in several ways, providing statistical summaries - for example summarizing all HTTP transactions, or all HTTP transactions to the HR Server. Note that data from different applications may not be summarized because:

- 1. The performance characteristics of different applications differ widely enough to render statistical analysis meaningless.
- 2. The responsiveness metrics of different applications may be different, making a statistical analysis impossible (in other words, one application may be transaction-oriented, while another is throughput-oriented).

Aggregating transactions collected over a period requires an aggregation algorithm. In this MIB Module, transaction aggregation always results in the following statistics:

TransactionCount

The total number of transactions during this period

SuccessfulTransactions

The total number of transactions that were successful. The management station can derive the percent success by dividing SuccessfulTransactions by the TransactionCount.

ResponsivenessMean

The average of the responsiveness metric for all aggregated transactions that completed successfully.

ResponsivenessMin

The minimum responsiveness metric for all aggregated transactions that completed successfully.

ResponsivenessMax

The maximum responsiveness metric for all aggregated transactions that completed successfully.

ResponsivenessBx

The count of successful transactions whose responsiveness metric fell into the range specified for Bx. There are 7 buckets specified. Because the performance of different applications varies widely, the bucket ranges are specified separately for each application (in the apmAppDirTable) so that they may be tuned to typical performance of each application.

For example, when aggregating the previous set of transactions by application we get (for simplicity the example only shows TransactionCount, SuccessfulTransactions, and ResponsivenessMean):

Application	Count 4	Successful	ResponsivenessMean 12 sec.
SAP/R3	1	1	17 sec.
FTP	1	1	212 Kbps.
RealVideo	1	1	100.0%

There are four different types of aggregation.

The flows(1) aggregation is the simplest. All transactions that share common application/server/client 3-tuples are aggregated together, resulting in a set of metrics for all such unique 3-tuples.

The clients(2) aggregation results in somewhat more aggregation (i.e., fewer resulting records). All transactions that share common application/client tuples are aggregated together, resulting in a set of metrics for all such unique tuples.

Waldbusser Standards Track [Page 5]

The servers(3) aggregation usually results in still more aggregation (i.e., fewer resulting records). All transactions that share common application/server tuples are aggregated together, resulting in a set of metrics for all such unique tuples.

The applications(4) aggregation results in the most aggregation (i.e., the fewest resulting records). All transactions that share a common application are aggregated together, resulting in a set of metrics for all such unique applications.

For example, if in a 5 minute period the following transactions occurred:

Actual Transactions:

#	App	Client	Server	Successful	Responsiveness
1	HTTP	Jim	CallCtr	N	_
2	HTTP	Jim	HR	Y	12 sec.
3	HTTP	Jim	Sales	Y	7 sec.
4	HTTP	Jim	CallCtr	Y	5 sec.
5	Email	Jim	Pop3	Y	12 sec.
6	HTTP	Jane	CallCtr	Y	3 sec.
7	SAP/R3	Jane	Finance	Y	19 sec.
8	Email	Jane	Pop3	Y	16 sec.
9	HTTP	Joe	HR	Y	18 sec.

The flows(1) aggregation results in the following table. Note that the first record (HTTP/Jim/CallCtr) is the aggregation of transactions #1 and #4:

Flow Aggregation:

J.									
App	Client	Server	Count	Succe- ssful	Rsp Mean	Rsp Min	Rsp Max	RspB1	RspB2
HTTP	Jim	CallCtr	2	1	5	5	5	1	0
HTTP	Jim	HR	1	1	12	12	12	0	1
HTTP	Jim	Sales	1	1	7	7	7	1	0
Email	Jim	Pop3	1	1	12	12	12	0	1
HTTP	Jane	CallCtr	1	1	3	3	3	1	0
SAP/R3	Jane	Finance	1	1	19	19	19	0	1
Email	Jane	Pop3	1	1	16	16	16	0	1
HTTP	Joe	HR	1	1	18	18	18	0	1

(Note: Columns above such as RspMean and RspB1 are abbreviations for objects in the apmReportTable)

The clients(2) aggregation results in the following table. Note that the first record (HTTP/Jim) is the aggregate of transactions #1, #2, #3 and #4:

Waldbusser Standards Track [Page 6]

Client Aggregation:

App	Client	Count	Succe- ssful	Rsp Mean	Rsp Min	Rsp Max	RspB1	RspB2
HTTP	Jim	4	3	8	5	12	2	1
Email	Jim	1	1	12	12	12	0	1
HTTP	Jane	1	1	3	3	3	1	0
SAP/R3	Jane	1	1	19	19	19	0	1
Email	Jane	1	1	16	16	16	0	1
HTTP	Joe	1	1	18	18	18	0	1

The servers(3) aggregation results in the following table. Note that the first record (HTTP/CallCtr) is the aggregation of transactions #1, #4 and #6:

Server Aggregation:

App	Server	Count	Succe- ssful	Rsp Mean	Rsp Min	Rsp Max	RspB1	RspB2
HTTP	CallCtr	3	2	4	3	5	2	0
HTTP	HR	2	2	15	12	18	0	2
HTTP	Sales	1	1	7	7	7	1	0
Email	Pop3	2	2	14	12	16	0	2
SAP/R3	Finance	1	1	19	19	19	0	1

The applications(4) aggregation results in the following table. Note that the first record (HTTP) is the aggregate of transactions #1, #2, #3, #5, #6 and #9:

Application Aggregation:

App	Count	Succe- ssful	Rsp Mean	Rsp Min	Rsp Max	RspB1	RspB2
HTTP	6	5	9	3	18	3	2
Email	2	2	14	12	16	0	2
SAP/R3	1	1	19	19	19	0	1

The apmReportControlTable provides for a historical set of the last 'X' reports, combining the historical records found in history tables with the periodic snapshots found in TopN tables. Conceptually the components are:

apmReportControlTable

Specifies data collection and summarization parameters, including the number of reports to keep and the size of each report.

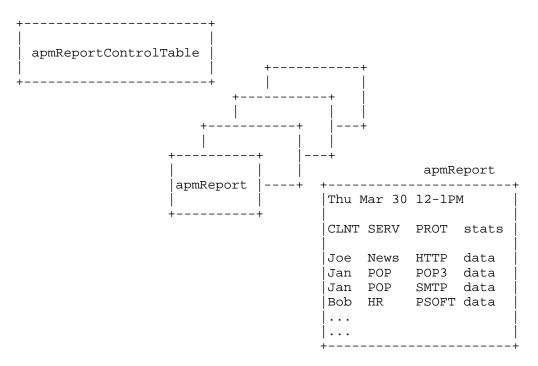

apmReport

Each APM Report contains an aggregated list of records that represent data collected during a specific time period.

Waldbusser Standards Track [Page 7]

An apmReportControlEntry causes a family of APM Reports to be created, where each report summarizes different, successive, contiguous periods of time.

While the conceptual model of APM Reports shows them as distinct entities, they are all entries in a single apmReportTable, where entries in report 'A' are separated from entries in report 'B' by different values of the apmReportIndex.

2.2. AppLocalIndex Linkages

The following set of example tables illustrates a few points:

- 1. How protocolDirEntries, apmHttpFilterEntries and apmUserDefinedAppEntries(not shown) all result in entries in the apmAppDirTable.
- 2. How a single appLocalIndex may be represented multiple times in the apmAppDirTable and apmReportTable if the agent measures multiple responsiveness types for that application.

A convention in the formatting of these tables is that the columns to the left of the $'\mid '$ separator are index columns for the table.

Waldbusser Standards Track [Page 8]

Assuming the following entries in the RMON2 protocolDirectory:

protocolDirectory

ID (*)	Parameters	LocalIndex
WWW	None	1
WWW Get	None	2
SAP/R3	None	3

(*) These IDs are represented here symbolically. Consult [5] for more detail in their format

and the following entry in the apmHttpFilterTable:

ApmHttpFilterTable

Index	AppLocalIndex	ServerAddress	URLPath	MatchType
5	20	hr.example.com	/expense	prefix(3)

the apmAppDirTable would be populated with the following entries:

apmAppDir

AppLocalIndex	ResponsivenessType	Config	
1	transaction(1)	On	
1	throughput(2)	On	
2	transaction(1)	On	
2	throughput(2)	On	
3	transaction(1)	On	
20	transaction(1)	On	
20	throughput(2)	On	

The entries in the apmAppDirTable with an appLocalIndex of 1, 2 and 3 correspond to the identically named entries in the protocolDirectory table. appLocalIndex #1 results in 2 entries, one to measure the transaction responsiveness of WWW and one to measure its throughput responsiveness. In contrast, appLocalIndex #3 results in only a transaction entry because the agent does not measure the throughput responsiveness for SAP/R3 (probably because it isn't very meaningful). Finally, appLocalIndex #20 corresponds to the entry in the apmHttpFilterTable and has transaction responsiveness and throughput responsiveness measurements available.

If a report was configured using application aggregation, entries in that report might look like:

apmReport	Table			
CtlIndex	Index	AppLocalIdx	ResponsivenessType	TransactionCount
1	1	1	transaction(1)	counters
1	1	1	throughput(2)	counters
1	1	2	transaction(1)	counters
1	1	2	throughput(2)	counters
1	1	3	transaction(1)	counters
1	1	20	transaction(1)	counters
1	1	20	throughput(2)	counters

Note that the index items protocolDirLocalIndex, apmReportServerAddress and apmReportClientID were omitted from apmReportTable example for brevity because they would have been equal to zero due to the use of the application aggregation in this example.

2.3. Measurement Methodology

There are many different measurement methodologies available for measuring application performance (e.g., probe-based, client-based, synthetic-transaction, etc.). This specification does not mandate a particular methodology - it is open to any that meet the minimum requirements. Conformance to this specification requires that the collected data match the semantics described herein. In particular, a data collection methodology must be able to measure response time, throughput, streaming responsiveness and availability as specified.

Note that in some cases a transaction may run for a long time but ultimately be successful. The measurement software shouldn't prematurely classify lengthy transactions as failures but should wait as long as the client application will wait for a successful response.

2.4. Instrumentation Architectures

Different architectural approaches and deployment strategies may be taken towards implementation of this specification. If a highly distributed approach is desired (e.g., an agent per desktop), one or both of the two approaches below may be used to make it more practical.

2.4.1. Application Directory Caching

It is necessary for the manager to have a copy of the tables that define the Application Directory in order to interpret APM measurements. It is likely that in a highly distributed network of

Waldbusser Standards Track [Page 10]

thousands of APM agents, this Application Directory will be the same on many, if not all of the agents. Repeated downloads of the Application Directory may be inefficient.

The apmAppDirID object is a single object that identifies the configuration of all aspects of the Application Directory when it is equal to a well-known, registered configuration. Thus, when a manager sees an apmAppDirID value that it recognizes, it need not download the Application Directory from that agent. In fact, the manager may discover a new registered Application Directory configuration on one agent and then re-use that configuration on another agent that shares the same apmAppDirID value.

Application directory registrations are unique within an administrative domain, allowing an administrator to create a custom application directory configuration without the need to assign it a globally-unique registration.

2.4.2. Push Model

When APM agents are installed on "desktops" (including laptops), a few issues make polling difficult:

- 1. Desktops often have dynamically-assigned addresses so there is no long-lived address to poll.
- 2. Desktops are not available as much as infrastructure components due to crashes, user-initiated reboots and shutdowns and user control over monitoring software. Thus a desktop may not be available to answer a poll at the moment when the manager is scheduled to poll that desktop.
- 3. Laptops that are connected via dialup connections are only sporadically connected and will routinely be unreachable when the manager is scheduled to poll.

As a consequence, a push model is usually more appropriate for desktop-based agents. To achieve this, the agent should follow the following rules in deciding what data to send in notifications.

Waldbusser Standards Track [Page 11]

APM Reports

If an agent wishes to push APM reports to a manager, it must send:

apmAppDirID

apmNameTable (any data updated since the last push) For each report the agent wishes to upload, it must send the entire apmReportControlEntry associated with that report and the associated entries in the apmReportTable that have changed since the last report.

APM Transactions

If an agent wishes to push APM transactions to a manager, it must send:

apmAppDirID

apmNameTable (any data updated since the last push)
apmTransactionTable (relevant entries)

APM Exceptions

The agent must send:

apmAppDirID

apmNameTable (any data updated since the last push)
apmTransactionEntry (of exception transaction)
apmExceptionEntry (entry that generated exception)
[Note that this list supersedes the information in the
OBJECTS clauses of the apmTransactionResponsivenessAlarm
and apmTransactionUnsuccessfulAlarm when the agent is
using a push model. This additional information
eliminates the need for the manager to request additional
data to understand the exception.]

The order of varbinds and where to segment varbinds into PDUs is at the discretion of the agent.

2.5. Structure of this MIB Module

The objects are arranged into the following groups:

- APM Application Directory Group
- APM User Defined Applications Group
- APM Report Group
- APM Transaction Group
- APM Exception Group
- APM Notification Group

These groups are the basic unit of conformance. If an agent implements a group, then it must implement all objects in that group. While this section provides an overview of grouping and conformance information for this MIB Module, the authoritative reference for such information is contained in the MODULE-COMPLIANCE and OBJECT-GROUP macros later in this MIB Module.

These groups are defined to provide a means of assigning object identifiers, and to provide a method for implementors of managed agents to know which objects they must implement.

2.5.1. The APM Application Directory Group

The APM Application Directory group contains configuration objects for every application or application verb monitored on this system. This group consists of the apmAppDirTable.

2.5.2. The APM User Defined Applications Group

The APM User Defined Applications Group contains objects that allow for the tracking of applications or application verbs that aren't registered in the protocolDirTable. This group consists of the apmHttpFilterTable and the apmUserDefinedAppTable.

2.5.3. The APM Report Group

The APM Report Group is used to prepare regular reports that aggregate application performance by flow, by client, by server, or by application. This group consists of the apmReportControlTable and the apmReportTable.

2.5.4. The APM Transaction Group

The APM Transaction Group is used to show transactions that are currently in progress and ones that have ended recently, along with their responsiveness metric.

Because many transactions last a very short time and because an agent may not retain completed transactions very long, transactions may exist in this table for a very short time. Thus, polling this table isn't an effective mechanism for retrieving all transactions unless the value of apmTransactionsHistorySize is suitably large for the transactions being monitored.

One important benefit of this table is that it allows a management station to check on the status of long-lived transactions. Because the apmReport and apmException mechanisms act only on transactions that have finished, a network manager may not have visibility for

Waldbusser Standards Track [Page 13]

some time into the performance of long-lived transactions such as streaming applications, large data transfers, or (very) poorly performing transactions. In fact, by their very definition, the apmReport and apmException mechanisms only provide visibility into a problem after nothing can be done about it. This group consists primarily of the apmTransactionTable.

2.5.5. The APM Exception Group

The APM Exception Group is used to generate immediate notifications of transactions that cross certain thresholds. The apmExceptionTable is used to configure which thresholds are to be checked for which types of transactions. The apmTransactionResponsivenessAlarm notification is sent when a transaction occurs with a responsiveness that crosses a threshold. The apmTransactionUnsuccessfulAlarm notification is sent when a transaction fails for which exception checking was configured. This group consists primarily of the apmExceptionTable.

2.5.6. The APM Notification Group

The APM Notification Group contains 2 notifications that are sent when thresholds in the APM Exception Table are exceeded.

AppLocalIndex ::= TEXTUAL-CONVENTION STATUS current

DESCRIPTION

apmGroups

"A locally arbitrary unique identifier associated with an application or application verb.

All objects of type AppLocalIndex are assigned by the agent out of a common number space. In other words, AppLocalIndex values assigned to entries in one table must not overlap with AppLocalIndex values assigned to entries in another table. Further, every protocolDirLocalIndex value registered by the agent automatically assigns the same value out of the

AppLocalIndex number space.

For example, if the protocolDirLocalIndex values { 1, 3, 5, 7 } have been assigned, and the apmHttpFilterAppLocalIndex values { 6, 8, 9 } have been assigned:

- Assignment of new AppLocalIndex values must not use the values { 1, 3, 5, 6, 7, 8, 9 }.
- AppLocalIndex values { 1, 3, 5, 7 } are automatically assigned and are associated with the identical value of protocolDirLocalIndex. In particular, an entry in the apmAppDirTable indexed by a value provides further information about a protocol indexed by the same value in the protocolDirTable of RMON2.

The value for each supported application must remain constant at least from one re-initialization of the entity's network management system to the next re-initialization, except that if an application is deleted and re-created, it must be re-created with a new value that has not been used since the last re-initialization.

The specific value is meaningful only within a given SNMP entity. An AppLocalIndex value must not be re-used until the next agent restart."

SYNTAX Unsigned32 (1..2147483647)

ProtocolDirNetworkAddress ::= TEXTUAL-CONVENTION STATUS current DESCRIPTION

"A network level address whose semantics and encoding are specified by an associated protocolDirLocalIndex value. Objects of this type must specify which protocolDirLocalIndex value is used. This value is encoded according to the encoding rules for the identified protocolDirectory entry.

For example, if the associated protocolDirLocalIndex indicates an encapsulation of ip, this object is encoded as a length octet of 4, followed by the 4 octets of the ip address, in network byte order.

Objects of this type may allow this value to be the zero length string. If so, they must identify they meaning of this value."

SYNTAX OCTET STRING (SIZE(0..255))

DataSourceOrZero ::= TEXTUAL-CONVENTION

Waldbusser Standards Track [Page 16]

STATUS current DESCRIPTION

"Identifies the source of the data that the associated function is configured to analyze. This source can be any interface on this device.

In order to identify a particular interface, this object shall identify the instance of the ifIndex object, defined in [4], for the desired interface.

For example, if an entry were to receive data from interface #1, this object would be set to ifIndex.1.

If the source of the data isn't an interface or cannot be localized to an interface, this object would be set to 0.0"

REFERENCE "The DataSource textual convention is defined in

RFC 2021 [5]."

SYNTAX OBJECT IDENTIFIER

RmonClientID ::= TEXTUAL-CONVENTION

STATUS current

DESCRIPTION

"A long-lived unique ID assigned to an end-system. This ID is assigned by the agent using an implementation-specific algorithm.

Because a client machine may be assigned multiple addresses over any time period it can be difficult to attribute behavior to a particular client based solely on its address. A ClientID may be assigned to provide a more stable handle for referencing that client. The entity that assigns the ClientID may use various implementation techniques to keep track of a client but if the assigning entity is unable to track client address mappings, it may map client identifiers to client addresses rather than to distinct client machines.

This is named ClientID because it helps to solve a problem seen in network clients (servers usually have well-known, long-lived addresses). However, ClientID's may be assigned to any end-system regardless of its role on the network."

SYNTAX Unsigned32 (0..4294967295)

[Page 17]

Waldbusser Standards Track

"Specifies one of 4 different techniques for aggregating transactions.

The metrics for a single transaction are the responsiveness of the transaction and whether the transaction succeeded (a boolean). When such metrics are aggregated in this MIB Module, these metrics are replaced by averages and distributions of responsiveness and availability. The metrics describing aggregates are constant no matter which type of aggregation is being performed. These metrics may be found in the apmReportTable.

The flows(1) aggregation is the simplest. All transactions that share common application/server/client 3-tuples are aggregated together, resulting in a set of metrics for all such unique 3-tuples.

The clients(2) aggregation results in somewhat more aggregation (i.e., fewer resulting records). All transactions that share common application/client tuples are aggregated together, resulting in a set of metrics for all such unique tuples.

The servers(3) aggregation usually results in still more aggregation (i.e., fewer resulting records). All transactions that share common application/server tuples are aggregated together, resulting in a set of metrics for all such unique tuples.

The applications(4) aggregation results in the most aggregation (i.e., the fewest resulting records). All transactions that share a common application are aggregated together, resulting in a set of metrics for all such unique applications.

Note that it is not meaningful to aggregate applications, as different applications have widely varying characteristics. As a result, this set of aggregations is complete."

```

apmAppDirTable OBJECT-TYPE
    SYNTAX SEQUENCE OF ApmAppDirEntry
   MAX-ACCESS not-accessible
   STATUS current
   DESCRIPTION
        "The APM MIB directory of applications and application
```

"The APM MIB directory of applications and application verbs. The agent will populate this table with all applications/verbs of any responsivenessType it has the capability to monitor. Since the agent populates this table with every entry it has the capability to monitor, the entries in this table are read-write, allowing the management station to modify parameters in this table but not to add new entries or delete entries (however, entries may be disabled). If new entries are added to the apmHttpFilterTable or the apmUserDefinedAppTable, the agent will add the corresponding entries to this table.

It is an implementation-dependent matter as to how the agent sets these default parameters. For example, it may leave certain entries in this table 'off(0)' if the agent developer

believes that combination will be infrequently used, allowing a manager that needs that capability to set it to 'on(1)'.

Some applications are registered in the RMON2 protocol directory and some are registered in other tables in this MIB Module. Regardless of where an application is originally registered, it is assigned an AppLocalIndex value that is the primary index for this table.

The contents of this table affect all reports and exceptions generated by this agent. Accordingly, modification of this table should be performed by a manager acting in the role of administrator. In particular, management software should not require or enforce particular configuration of this table - it should reflect the preferences of the site administrator, not the software author. As a practical matter, this requires management software to allow the administrator to configure the values it will use so that it can be adapted to the site policy."

               current
   DESCRIPTION
        "This object describes and configures the agent's support for
       application performance measurement for this application.
```

There are 3 types of measurements for different types of applications:

Transaction-Oriented applications have a fairly constant workload to perform for all transactions. The responsiveness metric for transaction-oriented applications is application response time (from first request to final delivery of service) and is measured in milliseconds. This is commonly referred to as end-user response time.

Throughput-Oriented applications have widely varying workloads based on the nature of the client request. In particular, throughput-oriented applications vary widely in the amount of data that must be transported to satisfy the request. The responsiveness metric for throughput-oriented applications is kilobits per second.

Streaming-Oriented applications deliver data at a constant metered rate of speed regardless of the responsiveness of the networking and computing infrastructure. This constant rate of speed is generally specified to be below (sometimes well below) the nominal capability of the infrastructure. However, when the infrastructures cannot deliver data at this speed, interruption of service or degradation of service can result. The responsiveness metric for streaming-oriented applications is the ratio of time that the service is degraded or interrupted to the total service time. This metric is measured in parts per million.

Note that for some applications, measuring more than one responsiveness type may be interesting. For agents that wish

```
to support more than one measurement for a application, they
       will populate this table with multiple entries for that
        application, one for each type."

::= { apmMibObjects 2 }

apmAppDirID OBJECT-TYPE

SYNTAX OBJECT IDENTIFIER MAX-ACCESS read-write STATUS current DESCRIPTION

"This object allows managers to avoid downloading application directory information when the directory is set to a known (usually fixed) configuration.

If the value of this object isn't 0.0, it signifies that the entire contents of the apmAppDirTable, apmHttpFilterTable, apmUserDefinedAppTable and protocolDirTable are equal to a known state identified by the value of this object. If a manager recognizes this value as identifying a directory configuration it has a local copy of, it may use this local copy rather than downloading these tables. Note that it may have downloaded this local copy (and the ID) from another agent and used this copy for all other agents that advertised the same ID.

If an agent recognizes that the entire contents of the apmAppDirTable, apmHttpFilterTable, apmUserDefinedAppTable and protocolDirTable are equal to a known state to which an ID has been assigned, it should set this object to that ID.

In many cases when this feature is used, the application directory information will be in read-only memory and thus the tables may not be modified via SNMP requests. In the event

Waldbusser Standards Track [Page 24]

that the tables are writable and a modification is made, the agent is responsible for setting this object to 0.0 if it cannot determine that the state is equal to a known state.

An agent is not obligated to recognize and advertise all such registered states as it may not have knowledge of all states. Thus, a manager may encounter agents whose DirectoryID value is 0.0 even though the contents of the directory were equal to a registered state.

Note that the contents of those tables includes the protocolDirLocalIndex and appLocalIndex values. In other words, these values can't be assigned randomly on each agent, but must be equal to values that are part of the known state. While it is possible for a manager to download application directory details using SNMP and to set the appropriate directoryID, the manager would need to have some scheme to ensure consistent values of LocalIndex variables from agent to agent. Such schemes are outside the scope of this specification.

Application directory registrations are unique within an administrative domain.

Typically these registrations will be made by an agent software developer who will set the application directory tables to a read-only state and assign a DirectoryID to that state. Thus, all agents running this software would share the same DirectoryID. As the application directory might change from one software release to the next, the developer may register different DirectoryID's for each software release.

A customer could also create a site-wide application directory configuration and assign a DirectoryID to that configuration as long as consistent values of LocalIndex variables can be ensured.

The value of this object must persist across reboots." ::= { apmMibObjects 3 }

-- APM HTTP Filter Table

-- The HTTP Filter Table creates virtual applications which measure the -- performance of certain web pages or sets of web pages. Some -- circumstances where this is particularly useful are:

- An Intranet or ASP scenario where a business application is running on one or more web pages or scripts.

```
(i.e., /expense/submit.cgi?employeeID=3426&...)
       - A web-hosting scenario where one wants to measure the
        service level for a particular customer
       - An e-commerce scenario where the performance of certain
         pages needs to be monitored more closely.
         (i.e., shopping cart, shipping, credit card authorization)

   SYNTAX SEQUENCE OF ApmNameEntry
   MAX-ACCESS not-accessible
   STATUS current
   DESCRIPTION
        "A client machine may have multiple addresses during a period
       of monitoring. The apmNameTable assigns a long-lived
       identifier to a client and records what addresses were
       assigned to that client for periods of time. Various
```

implementation techniques exist for tracking this mapping but if an agent is unable to track client address mappings, it may map client identifiers to client addresses rather than to distinct client machines.

A particular apmNameClientID should be a constant attribute of a particular client. When available, the agent may also record the machine name and/or user name which may be valuable for displaying to humans. The apmNameMachineName and apmNameUserName are relatively constant, changing only if these attributes actually change on the client.

The agent will store a historical log of these entries, aging out old entries as the log becomes too large. Since this table contains information vital to the interpretation of other tables (e.g., the apmReportTable), the agent should ensure that the log doesn't age out entries that would be referenced by data in those tables.

Note that an entry for a clientID is active from its StartTime until the StartTime of another entry (for the same clientID) that supersedes it, or 'now' if none supersede it. Therefore, if a clientID only has a single entry, it is by definition very new and should never be aged out. No entry for a clientID should be aged out unless it has been updated by a new entry for the client (i.e., with an updated address) and only if the new entry is 'old' enough.

To determine how old is old enough, compute the maximum value of Interval * (NumReports + 1) of all entries in the apmReportControlTable (the '+ 1' is to allow a reasonable period of time for the report to be downloaded). Then take the larger of this value and the age in seconds of the oldest entry in the current transaction table. If an entry for a clientID is superseded by another entry whose StartTime is more than this many seconds ago, then the older entry may be deleted."

        mapping. This ID is assigned by the agent using an
        implementation-specific algorithm."
    ::= { apmNameEntry 1 }
apmNameClientAddress OBJECT-TYPE
   SYNTAX ProtocolDirNetworkAddress (SIZE(1..255))
   MAX-ACCESS not-accessible
   STATUS current
   DESCRIPTION
        "The network client address for this client when this mapping
       was active.
       This is represented as an octet string with specific semantics
       and length as identified by the protocolDirLocalIndex
       component of the index. This object may not be the zero length
       string.
       Since this object is an index variable, it is encoded in the
        index according to the index encoding rules. For example, if
        the protocolDirLocalIndex component of the index indicates an
       encapsulation of ip, this object is encoded as a length octet
       of 4, followed by the 4 octets of the ip address, in network
       byte order. Care should be taken to avoid values of this
       object that, in conjunction with the other index variables,
       would result in an index longer than SNMP's maximum of 128
       subidentifiers."

```
SYNTAX TransactionAggregationType
-- INTEGER {
-- flows(1),
-- clients(2),
-- servers(3),
-- applications(4)
-- }
MAX-ACCESS read-create
STATUS current
DESCRIPTION
```

"The type of aggregation being performed for this set of reports.

The metrics for a single transaction are the responsiveness of the transaction and whether the transaction succeeded (a boolean). When such metrics are aggregated in this MIB Module, these metrics are replaced by averages and distributions of responsiveness and availability. The metrics describing aggregates are constant no matter which type of aggregation is being performed. These metrics may be found in the apmReportTable.

The flows(1) aggregation is the simplest. All transactions that share common application/server/client 3-tuples are aggregated together, resulting in a set of metrics for all such unique 3-tuples.

The clients(2) aggregation results in somewhat more aggregation (i.e., fewer resulting records). All transactions that share common application/client tuples are aggregated together, resulting in a set of metrics for all such unique tuples.

The servers(3) aggregation usually results in still more aggregation (i.e., fewer resulting records). All transactions that share common application/server tuples are aggregated together, resulting in a set of metrics for all such unique tuples.

The applications(4) aggregation results in the most aggregation (i.e., the fewest resulting records). All

Waldbusser Standards Track [Page 37]

transactions that share a common application are aggregated together, resulting in a set of metrics for all such unique applications.

Note that it is not meaningful to aggregate applications, as different applications have widely varying characteristics. As a result, this set of aggregations is complete.

```
This object may not be modified if the associated apmReportControlStatus object is equal to active(1)."
::= { apmReportControlEntry 3 }
```

apmReportControlInterval OBJECT-TYPE

SYNTAX Unsigned32
UNITS "Seconds"
MAX-ACCESS read-create
STATUS current
DESCRIPTION

"The interval in seconds over which data is accumulated before being aggregated into a report in the apmReportTable. All reports with the same apmReportControlIndex will be based on the same interval. This object must be greater than zero.

Many users desire that these reports be synchronized to within seconds of the beginning of the hour because the results may be correlated more meaningfully to business behavior and so that data from multiple agents is aggregated over the same time periods. Thus management software may take extra effort to synchronize reports to the beginning of the hour and to one another. However, the agent must not allow reports to 'drift' over time as they will quickly become unsynchronized. In particular, if there is any fixed processing delay between reports, the reports should deduct this time from the interval so that reports don't drift.

apmReportControlGrantedSize OBJECT-TYPE

SYNTAX Unsigned32 MAX-ACCESS read-only STATUS current

DESCRIPTION

"The number of entries per report the agent has allocated based on the requested amount in apmReportControlRequestedSize. Since multiple reports are saved, the total number of entries allocated will be this number multiplied by the value of apmReportControlGrantedReports, or 1 if that object doesn't exist.

When the associated apmReportControlRequestedSize object is created or modified, the agent should set this object as closely to the requested value as is possible for the particular implementation and available resources. When considering resources available, the agent must consider its ability to allocate this many entries for all reports.

Note that while the actual number of entries stored in the reports may fluctuate due to changing conditions, the agent must continue to have storage available to satisfy the full report size for all reports when necessary. Further, the agent must not lower this value except as a result of a set to the associated apmReportControlRequestedSize object."

::= { apmReportControlEntry 6 }

MAX-ACCESS read-only STATUS current

DESCRIPTION

"The number of the report in progress. When an apmReportControlEntry is activated, the first report will be numbered one."

::= { apmReportControlEntry 10 }

apmReportControlDeniedInserts OBJECT-TYPE

SYNTAX Counter32
MAX-ACCESS read-only
STATUS current
DESCRIPTION

"The number of failed attempts to add an entry to reports for

Waldbusser Standards Track [Page 40]

this apmReportControlEntry because the number of entries would have exceeded apmReportControlGrantedSize.

This number is valuable in determining if enough entries have been allocated for reports in light of fluctuating network usage. Note that since an entry that is denied will often be attempted again, this number will not predict the exact number of additional entries needed, but can be used to understand the relative magnitude of the problem.

Also note that there is no ordering specified for the entries in the report, thus there are no rules for which entries will be omitted when not enough entries are available. As a consequence, the agent is not required to delete 'least valuable' entries first."

::= { apmReportControlEntry 11 }

apmReportControlDroppedFrames OBJECT-TYPE

SYNTAX Counter32
MAX-ACCESS read-only
STATUS current
DESCRIPTION

"The total number of frames which were received by the agent and therefore not accounted for in the *StatsDropEvents, but for which the agent chose not to count for this entry for whatever reason. Most often, this event occurs when the agent is out of some resources and decides to shed load from this collection.

This count does not include packets that were not counted because they had MAC-layer errors.

This counter is only relevant if this apm report is based on a data source whose collection methodology is based on analyzing network traffic.

Note that if the apmReportTables are inactive because no applications are enabled in the application directory, this value should be 0.

Note that, unlike the dropEvents counter, this number is the exact number of frames dropped."

    ::= { apmMibObjects 10 }
apmReportEntry OBJECT-TYPE
   SYNTAX
              ApmReportEntry
   MAX-ACCESS not-accessible
```

STATUS current DESCRIPTION

"A conceptual row in the apmReportTable.

The apmReportControlIndex value in the index identifies the apmReportControlEntry on whose behalf this entry was created. The apmReportIndex value in the index identifies which report (in the series of reports) this entry is a part of. The apmAppDirAppLocalIndex value in the index identifies the common application of the transactions aggregated in this entry.

The apmAppDirResponsivenessType value in the index identifies the type of responsiveness metric reported by this entry and uniquely identifies this entry when more than one responsiveness metric is measured for a flow. Entries will only exist in this table for those combinations of AppLocalIndex and ResponsivenessType that are configured 'on(1)'.

The protocolDirLocalIndex value in the index identifies the network layer protocol of the apmReportServerAddress. When the associated apmReportControlAggregationType value is equal to applications(4) or clients(2), this protocolDirLocalIndex value will equal 0.

The apmReportServerAddress value in the index identifies the network layer address of the server in transactions aggregated in this entry.

The apmNameClientID value in the index identifies the client in transactions aggregated in this entry. If the associated apmReportControlAggregationType is equal to applications(4) or servers(3), then this protocolDirLocalIndex value will equal 0.

An example of the indexing of this entry is apmReportTransactionCount.3.15.3.1.8.4.192.168.1.2.3232235788

Note that some combinations of index values may result in an index that exceeds 128 sub-identifiers in length which exceeds the maximum for the SNMP protocol. Implementations should take care to avoid such combinations."

The apmAppDirResponsivenessType value in the index identifies the type of responsiveness metric reported by this entry and uniquely identifies this entry when more than one responsiveness metric is measured for a flow. Entries will only exist in this table for those combinations of AppLocalIndex and ResponsivenessType that are configured 'on(1)'.

The protocolDirLocalIndex value in the index identifies the network layer protocol of the apmTransactionServerAddress. The apmTransactionServerAddress value in the index identifies the network layer address of the server in the transaction represented by this entry.

The apmNameClientID value in the index identifies the client in the transaction represented by this entry.

An example of the indexing of this entry is apmTransactionCount.3.1.8.4.192.168.1.2.3232235788.2987

Note that some combinations of index values may result in an index that exceeds 128 sub-identifiers in length which exceeds the maximum for the SNMP protocol. Implementations should take care to avoid such combinations."

```
INDEX { apmAppDirAppLocalIndex,
          apmAppDirResponsivenessType,
          protocolDirLocalIndex, apmTransactionServerAddress,

```

apmThroughputExceptionMinTime OBJECT-TYPE

SYNTAX Unsigned32
UNITS "seconds"
MAX-ACCESS read-write
STATUS current

DESCRIPTION

"Because the responsiveness for throughput-oriented transactions is divided by the elapsed time, it can be very sensitive to short-term performance variations for transactions that take a short period of time. For example, when downloading a very short file, a single dropped packet could double or triple the total response time.

Further, throughput is usually examined for applications that transfer a lot of data, and when doing so it is helpful to conceptualize transaction costs that are proportional to the amount of data separately from those costs that are relatively fixed (i.e., independent of the amount of data). For very short transactions, these fixed transaction costs (handshake, setup time, authentication, round-trip time) may dominate the total response time for the transaction, resulting in throughput measurements that aren't really proportional to the network's, server's and client's combined data throughput capability.

This object controls the minimum number of seconds that an throughput-based transaction must exceed before an exception can be generated for it. If this object is set to zero, then all throughput-based transactions are candidates for exceptions.

```
The value of this object must persist across reboots."

4. Security Considerations

END

There are a number of management objects defined in this MIB module with a MAX-ACCESS clause of read-write and/or read-create. Such objects may be considered sensitive or vulnerable in some network environments. The support for SET operations in a non-secure environment without proper protection can have a negative effect on network operations.

Specifically, most of the read-write and read-create objects in this MIB module may be used to configure an agent to reveal network addresses, application usage information and conversation statistics that may be considered sensitive in some environments.

Some of the readable objects in this MIB module (i.e., objects with a MAX-ACCESS other than not-accessible) may be considered sensitive or vulnerable in some network environments. It is thus important to control even GET and/or NOTIFY access to these objects and possibly to even encrypt the values of these objects when sending them over the network via SNMP.

Waldbusser Standards Track [Page 58]

Specifically, this MIB contains network addresses, machines names, user names, application usage information, and conversation statistics. Data of this nature should be considered sensitive and the privacy of the users from whom it was gathered protected. Administrators should restrict read access to this data to specifically authorized individuals or agents that recognize the privacy implications of its release. In situations where read access to this data cannot be restricted, it should not be gathered.

Systems that implement the objects in this MIB module have the capability of measuring the time taken to execute transactions. Depending on the transaction type, some or all of this transaction time may be associated with the time taken to perform security calculations. Such data may help an attacker to use timing attacks to extract secrets from the systems involved in the transactions. See [10] for more information.

SNMP versions prior to SNMPv3 did not include adequate security. Even if the network itself is secure (for example by using IPSec), even then, there is no control as to who on the secure network is allowed to access and GET/SET (read/change/create/delete) the objects in this MIB module.

It is RECOMMENDED that implementers consider the security features as provided by the SNMPv3 framework (see [8], section 8), including full support for the SNMPv3 cryptographic mechanisms (for authentication and privacy).

Further, deployment of SNMP versions prior to SNMPv3 is NOT RECOMMENDED. Instead, it is RECOMMENDED to deploy SNMPv3 and to enable cryptographic security. It is then a customer/operator responsibility to ensure that the SNMP entity giving access to an instance of this MIB module is properly configured to give access to the objects only to those principals (users) that have legitimate rights to indeed GET or SET (change/create/delete) them.

Information on the procedures with respect to rights in RFC documents can be found in BCP 78 and BCP 79.

Copies of IPR disclosures made to the IETF Secretariat and any assurances of licenses to be made available, or the result of an attempt made to obtain a general license or permission for the use of such proprietary rights by implementers or users of this specification can be obtained from the IETF on-line IPR repository at http://www.ietf.org/ipr.

The IETF invites any interested party to bring to its attention any copyrights, patents or patent applications, or other proprietary rights that may cover technology that may be required to implement this standard. Please address the information to the IETF at ietf-ipr@ietf.org.
