November 25, 1996
<http://www.cs.arizona.edu/icon/docs/ipd278.html>

1. Introduction

The current version of Icon is Version 9.3 and is described in the third edition of the Icon book [1]. This document supplements the second edition of the Icon book [2], which describes Version 8.0.

Most of the language extensions in Version 9.3 are upward-compatible with previous versions of Icon and most programs written for earlier versions work properly under Version 9.3. The language additions to Version 9.3 are:

- a preprocessor
- graphics facilities for some platforms
- new functions and keywords
- several other changes and enhancements

There also are several improvements to the implementation. See Section 3.

2. Language Features

2.1 Preprocessing

All Icon source code passes through a preprocessor before translation. The effects of preprocessing can be seen by running `icont` or `iconc` with the `-E` flag.

Preprocessor directives control the actions of the preprocessor and are not passed to the Icon translator or compiler. If no preprocessor directives are present, the source code passes through the preprocessor unaltered.

A source line is a preprocessor directive if its first non-whitespace character is a `$` and if that `$` is not followed by another punctuation character. The general form of a preprocessor directive is

```
$ directive arguments # comment
```

Whitespace separates tokens when needed, and case is significant, as in Icon proper. The entire preprocessor

directive must appear on a single line which cannot be continued. The comment portion is optional. An invalid preprocessor directive produces an error except when skipped by conditional compilation.

Preprocessor directives can appear anywhere in an Icon source file without regard to procedure, declaration, or expression boundaries.

Include Directives

An include directive has the form

```
$include filename
```

An include directive causes the contents of another file to be interpolated in the source file. The file name must be quoted if it is not in the form of an Icon identifier. `#line` comments are inserted before and after the included file to allow proper identification of errors.

Included files may be nested to arbitrary depth, but a file may not include itself either directly or indirectly. File names are looked for first in the current directory and then in the directories listed in the environment variable `LPATH`. Relative paths are interpreted in the preprocessor's context and not in relation to the including file's location.

Line Directives

A line directive has the form

```
$line n [filename]
```

The line containing the preprocessing directive is considered to be line `n` of the given file (or the current file, if unspecified) for diagnostic and other purposes. The line number is a simple unsigned integer. The file name must be quoted if it is not in the form of an Icon identifier.

Note that the interpretation of `n` differs from that of the C preprocessor, which interprets it as the number of the next line. `$line` is an alternative form of the older, special comment form `#line`. The preprocessor recognizes both forms and produces the fully specified older form for the lexical analyzer.

Define Directives

A define directive has the form

```
$define name text
```

The define directive defines the text to be substituted for later occurrences of the identifier name in the source code. `text` is any sequence of characters except that any string or cset literals must be properly terminated within the definition. Leading and trailing whitespace are not part of the definition. The text can be empty.

Redefinition of a name is allowed only if the new text is exactly the same as the old text. For example, `3.0` is not the same as `3.000`.

Redefinition of Icon's reserved words and keywords is allowed but not advised.

Definitions remain in effect through the end of the current original source file, crossing include boundaries, but they do not persist from file to file when multiple names are given on the command line.

If the text of a definition is an expression, it is wise to parenthesize it so that precedence causes no problems when it is substituted. If the text begins with a left parenthesis, it must be separated from the name by at least one space. Note that the Icon preprocessor, unlike the C preprocessor, does not provide parameterized

definitions.

Undefine Directives

An undefine directive has the form

```
$undef name
```

The current definition of `name` is removed, allowing its redefinition if desired. It is not an error to undefine a non-existent name.

Predefined Symbols

At the start of each source file, several symbols are automatically defined to indicate the Icon system configuration. Each potential predefined symbol corresponds to one of the values produced by the keyword `&features`. If a feature is present, the symbol is defined with a value of 1. If a feature is absent, the symbol is not defined. See Appendix A for a list of predefined symbols.

Predefined symbols have no special status: like other symbols, they can be undefined and redefined.

Substitution

As input is read, each identifier is checked to see if it matches a previous definition. If it does, the value replaces the identifier in the input stream.

No whitespace is added or deleted when a definition is inserted. The replacement text is scanned for defined identifiers, possibly causing further substitution, but recognition of the original identifier name is disabled to prevent infinite recursion.

Occurrences of defined names within comments, literals, or preprocessor directives are not altered.

The preprocessor is ignorant of multi-line literals and can potentially be fooled this way into making a substitution inside a string constant.

The preprocessor works hard to get line numbers right, but column numbers are likely to be rendered incorrect by substitutions.

Substitution cannot produce a preprocessor directive. By then it is too late.

Conditional Compilation

Conditional compilation directives have the form

```
$ifdef name
```

and

```
$ifndef name
```

`$ifdef` or `$ifndef` cause subsequent code to be accepted or skipped depending on whether `name` has been previously defined. `$ifdef` succeeds if a definition exists; `$ifndef` succeeds if a definition does not exist. The value of the definition does not matter.

A conditional block has this general form:

```
$ifdef name or $ifndef name
```

```
... code to use if test succeeds ...
$else
... code to use if test fails ...
$endif
```

The `$else` section is optional. Conditional blocks can be nested provided that all of the `$if/$else/$endif` directives for a particular block are in the same source file. This does not prevent the conditional inclusion of other files via `$include` as long as any included conditional blocks are similarly self-contained.

Error Directives

An error directive has the form

```
$error text
```

An `$error` directive forces a fatal compilation error displaying the given text. This is typically used with conditional compilation to indicate an improper set of definitions.

Subtle Points

Because substitution occurs on replacement text but not on preprocessor directives, either of the following sequences is valid:

```
$define x 1      $define y x
$define y x      $define x 1
write(y)         write(y)
```

It is possible to construct pathological examples of definitions that combine with the input text to form a single Icon token, as in

```
$define X e3     $define Y 456e
write(123X)      write(Y+3)
```

2.2 Graphics Facilities

Version 9.3 provides graphics facilities through a combination of high-level support and a repertoire of functions. Not all platforms support graphics. Consult the current reference manual [3].

2.3 New Functions and Keywords

The new functions and keywords are described briefly here. Appendix B contains more complete descriptions in the style of the second edition of the Icon book.

There are six new functions:

<code>chdir(s)</code>	Changes the current directory to <code>s</code> but fails if there is no such directory or if the change cannot be made.
<code>delay(i)</code>	Delays execution <code>i</code> milliseconds. Delaying execution is not supported on all platforms; if it is not, there is no delay and <code>delay()</code> fails.
<code>function()</code>	Generates the names of the Icon (built-in) functions.
<code>loadfunc(s1, s2)</code>	Dynamically loads a C function. This

function presently is supported on a few UNIX systems. See [4] for details.

<code>serial(X)</code>	Produces the serial number of X if it is a type that has one.
<code>sortf(X, i)</code>	Produces a sorted list of the elements of X. The results are similar to those of <code>sort(X, i)</code> , except that among lists and among records, structure values are ordered by comparing their <i>i</i> th fields.

There are six new keywords:

<code>&allocated</code>	Generates the number of bytes allocated since the beginning of program execution. The first result is the total number of bytes in all regions, followed by the number of bytes in the static, string, and block regions.
<code>&dump</code>	If the value of <code>&dump</code> is nonzero at program termination, a dump in the style of <code>display()</code> is provided.
<code>&e</code>	The base of the natural logarithms, 2.71828 ...
<code>&phi</code>	The golden ratio, 1.61803 ...
<code>&pi</code>	The ratio of the circumference of a circle to its diameter, 3.14159 ...
<code>&progname</code>	The file name of the executing program. <code>&progname</code> is a variable and a string value can be assigned to it to replace its initial value.

The graphics facilities add additional new keywords [3].

Some UNIX platforms now support the keyboard functions `getch()`, `getche()`, and `kbhit()`. Whether or not these functions are supported can be determined from the values generated by `&features`. Note: On UNIX platforms, "keyboard" input comes from standard input, which may not necessarily be the keyboard. Warning: The keyboard functions under UNIX may not work reliably in all situations and may leave the console in a strange mode if interrupted at an unfortunate time. These potential problems should be kept in mind when using these functions.

2.4 Other Language Enhancements

Lists

The functions `push()` and `put()` now can be called with multiple arguments to add several values to a list at one time. For example,

```
put(L, x1, x2, x3)
```

appends the values of `x1`, `x2`, and `x3` to `L`. In the case of `push()`, values are prepended in order that they appear from left to right. Consequently, as a result of

```
push(L, x1, x2, x3)
```

the first (leftmost) item on `L` is the value of `x3`.

Records

Records can now be sorted by `sort()` and `sortf()` to produce sorted lists of the record fields.

A record can now be subscripted by the string name of one of its fields, as in

```
z["r"]
```

which is equivalent to

```
z.r
```

If the named field does not exist for the record, the subscripting expression fails.

Records can now be used to supply arguments in procedure invocation, as in

```
p ! R
```

which invokes `p` with arguments from the fields of `R`.

Multiple Subscripts

Multiple subscripts are now allowed in subscripting expressions. For example,

```
x[i, j, k]
```

is equivalent to

```
x[i][j][k]
```

`x` can be a string, list, table, or record.

Integers

The sign of an integer is now preserved when it is shifted right with `ishift()`.

The form of approximation for large integers that appear in diagnostic messages now indicates a power of ten, as in `10^57`. The approximation is now accurate to the nearest power of 10.

Named Functions

The function `proc(x, i)` has been extended so that `proc(x, 0)` produces the built-in function named `x` even if the global identifier having that name has been assigned another value. `proc(x, 0)` fails if `x` is not the name of a function.

String Invocation

String invocation can now be used for assignment operations, as in

```
" := "(x, 3)
```

which assigns 3 to `x`.

2.5 Other Changes

- The ability to configure Icon so that Icon procedures can be called from a C program has been eliminated.
- Memory monitoring and the functions associated with it no longer are supported.
- The `dynamic` declaration, a synonym for `local`, is no longer supported.
- Real literals that are less than 1 no longer need a leading zero. For example, `.5` now is a valid real literal instead of being the dereferencing operator applied to the integer 5.
- A reference to an unknown record field no longer produces an error during linking. Instead a reference to an unknown field at run-time causes error termination.
- The identifiers listed by `display()` are now given in sorted order.
- In sorting structures, records now are first sorted by record name and then by age (serial number).
- Some of the values generated by `&features` have been changed, and some former values corresponding the features that are present in all implementations of Icon have been deleted. The corresponding pre-defined constants have been deleted. See Appendix A.
- The text of some run-time error messages has been changed and a few new error numbers have been added. A complete list is available on request.

3. Implementation Changes

Linker Changes

By default, unreferenced globals (including procedures and record constructors) are now omitted from the code generated by `icont`. This may substantially reduce the size of icode files, especially when a package of procedures is linked but not all the procedures are used.

The `invocable` declaration and the command-line options `-f s` and `-v n` are now honored by `icont` as well as `iconc` [5]. The `invocable` declaration can be used to prevent the removal of specific unreferenced procedures and record constructors that are invoked by string invocation. The `-f s` option prevents the removal of all unreferenced declarations and is equivalent to `invocable all`.

The command line option `-v n` to `icont` controls the verbosity of its output:

`-v 0` is the same as `icont -s`

`-v 1` is the default

`-v 2` reports the sizes of the icode sections (procedures, strings, and so forth)

`-v 3` also lists discarded globals

Note: Programs that use string invocation may malfunction if the default removal of declarations is used. The safest and easiest approach is to add

```
invocable all
```

to such programs.

Other Changes

- The tables used by `icont` now expand automatically. The `-s` option is no longer needed. As a side effect of this change, the sizes of procedures are no longer listed during translation.
- All implementations of Icon now use fixed-sized storage regions. Multiple regions are allocated if needed.
- Under UNIX, shell headers are now produced instead of bootstrapping code in icode files. This substantially reduces the size of icode files on some platforms.
- Under MS-DOS, `iconx` now finds icode files at any place on the `PATH` specification as well as in the current directory. The MS-DOS translator now is also capable of producing `.exe` files.

4. Limitations, Bugs, and Problems

- Line numbers sometimes are wrong in diagnostic messages related to lines with continued quoted literals.
- Large-integer arithmetic is not supported in `i to j` and `seq()`. Large integers cannot be assigned to integer-valued keywords.
- Large-integer literals are constructed at run-time. Consequently, they should not be used in loops where they would be constructed repeatedly.
- Conversion of a large integer to a string is quadratic in the length of the integer. Conversion of a very large integer to a string may take a very long time and give the appearance of an endless loop.
- Integer overflow on exponentiation may not be detected during execution. Such overflow may occur during type conversion.
- In some cases, trace messages may show the return of subscripted values, such as `&null[2]`, that would be erroneous if they were dereferenced.
- If a long file name for an Icon source-language program is truncated by the operating system, mysterious diagnostic messages may occur during linking.
- Stack overflow checking uses a heuristic that is not always effective.
- If an expression such as

```
x := create expr
```

is used in a loop, and `x` is not a global variable, unreferenceable co-expressions are generated by each successive `create` operation. These co-expressions are not garbage collected. This problem can be circumvented by making `x` a global variable or by assigning a value to `x` before the `create` operation, as in

```
x := &null
x := create expr
```

- Stack overflow in a co-expression may not be detected and may cause mysterious program malfunction.

In addition, the symbol `_v9` is defined in Version 9.

Appendix B -- New Functions and Keywords

`chdir(s)` : `n` -- change directory

`chdir(s)` changes the directory to `s` but fails if there is no such directory or if the change cannot be made. Whether the change in the directory persists after program termination depends on the operating system on which the program runs.

Error: 103 `s` not string

`delay(i)` : `n` -- delay execution

`delay(i)` delays execution `i` milliseconds. This function is not supported on all platforms; if it is not, there is no delay and `delay()` fails.

Error: 101 `i` not integer

`flush(f)` : `n` -- flush buffer

`flush(f)` flushes the output buffers for `f`.

Error: 105 `f` not file

`function()` : `s1, s2, ..., s` -- generate function names

`function()` generates the names of the Icon (built-in) functions.

`loadfunc(s1, s2)` : `p` -- load external function

`loadfunc(s1, s2)` loads the function named `s2` from the library file `s1`. `s2` must be a C or compatible function that provides a particular interface expected by `loadfunc()`. `loadfunc()` is not available on all systems.

`proc(x, i)` : `p` -- convert to procedure

`proc(x, i)` produces a procedure corresponding to the value of `x`, but fails if `x` does not correspond to a procedure. If `x` is the string name of an operator, `i` specifies the number of arguments: 1 for unary (prefix), 2 for binary (infix) and 3 for ternary. `proc(x, 0)` produces the built-in function named `x` even if the global identifier having that name has been assigned another value. `proc(x, 0)` fails if `x` is not the name of a function.

Default: `i` 1

Errors: 101 `i` not integer
 205 `i` not 0, 1, 2, or 3

`push(L, x1, x2, ..., xn) : L -- push onto list`

`push(L, x1, x2, ..., xn)` pushes `x1, x2, ..., xn` onto the left end of `L`. Values are pushed in order from left to right, so `xn` becomes the first (leftmost) value on `L`. `push(L)` with no second argument pushes a null value onto `L`.

Errors: 108 L not list
307 inadequate space in block region

See also: `get()`, `pop()`, `pull()`, and `put()`

`put(L, x1, x2, ..., xn) : L -- put onto list`

`put(L, x1, x2, ..., xn)` puts `x1, x2, ..., xn` onto the right end of `L`. Values are pushed in order from left to right, so `xn` becomes the last (rightmost) value on `L`. `put(L)` with no second argument puts a null value onto `L`.

Errors: 108 L not list
307 inadequate space in block region

See also: `get()`, `pop()`, `pull()`, and `push()`

`serial(x) : s -- produce serial number`

`serial(x)` produces the serial number of `x` if it is a type that has one but fails otherwise.

`sort(X, i) : L -- sort structure`

`sort(X, i)` produces a list containing values from `x`. If `x` is a list, record, or set, `sort(X, i)` produces the values of `x` in sorted order. If `x` is a table, `sort(X, i)` produces a list obtained by sorting the elements of `x`, depending on the value of `i`. For `i = 1` or `2`, the list elements are two-element lists of key/value pairs. For `i = 3` or `4`, the list elements are alternative keys and values. Sorting is by keys for `i` odd, by value for `i` even.

Default: i 1

Errors: 101 i not integer
115 X not structure
205 i not 1, 2, 3, or 4
307 inadequate space in block storage region

See also: `sortf()`

`sortf(X, i) : L -- sort structure by field`

`sortf(X, i)` produces a sorted list of the values in `x`. Sorting is primarily by type and in most respects is the same as with `sort(X, i)`. However, among lists and among records, two structures are ordered by comparing their `i`th fields. `i` can be negative but not zero. Two structures having equal `i`th fields are ordered as they would be in regular sorting, but structures lacking an `i`th field appear before structures having them.

Default: i 1

Errors: 101 i not integer
126 X not list, record, or set
205 i = 0
307 inadequate space in block region

See also: `sort()`

`&allocated` : `i1, i2, i3, i4` -- cumulative allocation

`&allocated` generates the total amount of space, in bytes, allocated since the beginning of program execution. The first value is the total for all regions, followed by the totals for the static, string, and block regions, respectively. The space allocated in the static region is always given as zero. Note: `&allocated` gives the cumulative allocation; `&storage` gives the current allocation; that is, the amount that has not been freed by garbage collection.

`&dump` : `i` -- termination dump

If the value of `&dump` is nonzero when program execution terminates, a dump in the style of `display()` is provided.

`&e` : `r` -- base of natural logarithms

The value of `&e` is the base of the natural logarithms, 2.71828

`&phi` : `r` -- golden ratio

The value of `&phi` is the golden ratio, 1.61803

`&pi` : `r` -- ratio of circumference to diameter of a circle

The value of `&pi` is the ratio of the circumference of a circle to its diameter, 3.14159

`&progname` : `s` -- program name

The value of `&progname` is the file name of the executing program. A string value can be assigned to `&progname` to replace its initial value.
