1 Introduction

This package defines commands to access bold math symbols. The basic command is \bm which may be used to make the math expression in its argument be typeset using bold fonts.

The syntax of \bm is:
\bm{⟨math expression⟩}
So $\alpha \not= \bm{\alpha}$ produces $\alpha \not= \alpha$.

\bm goes to some trouble to preserve the spacing, so that for instance \bm< is a bold < but with the correct \mathrel spacing that \TeX gives to <. The calculations that \TeX needs to do for \bm can be quite involved and so a definition form is provided.

\DeclareBoldMathCommand[⟨math version⟩]{⟨cmd⟩}{⟨math expression⟩}
Defines \cmd to be the bold form of the math expression. The ⟨math version⟩ defaults to ‘bold’ (i.e., \boldmath).

For relatively simple expressions, the resulting definitions are very efficient, for instance after:
\DeclareBoldMathCommand[bold]{\alpha}{\balpha}
\balpha is a single ‘mathchardef’ token producing a bold alpha, and so is just as fast to execute as \alpha.

The above command is mainly intended for use in packages. For occasional use in \LaTeX documents, and for compatibility with the plain \TeX support for the mathtime fonts, a ‘user-level’ version, \bmdefine is provided that is equivalent to:
\DeclareBoldMathCommand[bold]{\alpha}{\balpha}

If there is a ‘heavy’ math version defined (usually accessed by a user-command \heavymath) then a similar command \hm is defined which accesses these ‘ultra bold’ fonts. Currently this is probably only useful with the ‘mathtime plus’ font collection. Definitions of commands that use these fonts may be made by specifying the optional argument ‘heavy’ to \DeclareBoldMathCommand. Again an
abbreviation, \texttt{\textbackslash{}hmdefine}, is provided, equivalent to:
\texttt{\textbackslash{}DeclareBoldMathCommand\[heavy\].}

The command names (but not the implementation) are taken from Michael Spivak’s macros to support the mathtime fonts for plain \TeX. In those original macros, the syntax for \texttt{\textbackslash{}hmdefine} was \texttt{\textbackslash{}hmdefine\[\textbackslash{}bm\]alpha\{\textbackslash{}bm\}alpha} (with a nested \texttt{\textbackslash{}bm}). This syntax also works with this package.

2 Font allocation

In order to access bold fonts in the simplest and quickest possible manner, the package normally allocates symbol fonts for bold (and possibly heavy) fonts into the ‘normal’ math version. By default it allocates at most four fonts for \texttt{\textbackslash{}bm} and at most three fonts for \texttt{\textbackslash{}hm}. This means that if the mathtime plus font set is being used, seven additional symbol fonts will be used, in addition to the basic four that \LaTeX already declares. The mathtime package also declares an extra symbol font, bringing the total to twelve. The maximum number of symbol and math alphabet fonts that can be used in a math version is sixteen. So the above allocation scheme does not leave room for many extra math symbols (such as the AMS symbols) or math alphabets (such as \texttt{\textbackslash{}mathit}).

Before loading the \texttt{\textbackslash{}bm} package you may define \texttt{\textbackslash{}bm\textbackslash{}max} and \texttt{\textbackslash{}hm\textbackslash{}max} to be suitable values, for instance you may want to set \texttt{\textbackslash{}newcommand\textbackslash{}hm\textbackslash{}max\{0\}} if you will not be using \texttt{\textbackslash{}hm} much, but you do have a heavy math version defined.

Even if \texttt{\textbackslash{}bm\textbackslash{}max} is set to zero, \texttt{\textbackslash{}bm} will still access the correct bold fonts (by accessing the fonts via \texttt{\textbackslash{}boldmath}) but this method is slower, and does not work with delimiters. Delimiters can only be made bold if the bold font has been allocated.

Conversely if you have a non standard font set that makes available extra math delimiters and accents in bold and medium weights you may want to \textit{increase} \texttt{\textbackslash{}bm\textbackslash{}max} so that fonts are allocated for your font set.

3 Features

In most cases this package should work in a fairly self-explanatory way, but there are some things that might not be obvious.

3.1 Interaction with Math Alphabet Commands

As mentioned above, \texttt{\textbackslash{}bm} goes to some trouble to try to make a command that is just like its argument, but using a bold font. This does not always produce the effect that you might expect.

\begin{verbatim}
\textbackslash{}$1 \ g \ \textbackslash{}bm\{g\}$
\textbackslash{}$2 \ \texttt{\textbackslash{}mathrm\{g \ \textbackslash{}bm\{g\}\}}$
\textbackslash{}$3 \ \{g\} \ \texttt{\textbackslash{}bm\{\{g\}\}}$
\textbackslash{}$4 \ \texttt{\textbackslash{}mathrm\{\{g\} \ \textbackslash{}bm\{\{g\}\}\}}$
\textbackslash{}$5 \ \texttt{\textbackslash{}mathrm\{g\} \ \textbackslash{}bm\{\texttt{\textbackslash{}mathrm\{g\}\}}}$
\end{verbatim}

produces the following:

$1\ g \ 2g \ 3g \ 4g \ 5g$
In math mode ‘g’ is effectively a command that produces the letter ‘g’ from the ‘letters’ alphabet, unless a Math Alphabet command is in effect, in which case the ‘g’ comes from the specified alphabet. \textbf{bm}{g} makes an equivalent command, but which defaults to a bold letter alphabet. So in the first example \textbf{bm}{g} is bold math italic, but in the second example the \textbf{mathrm} applies to both g and \textbf{bm}{g} in the same way, and so they are both roman.

\textbf{bm} only inspects the ‘top level’ definition of a command, for more complicated expressions, and anything inside a \{ } group, \textbf{bm} forces bold fonts by essentially the same (slow) technique used by the AMS \textbf{boldsymbol} command (but \textbf{bm} still takes more care of the spacing). So the third example produces identical output to the first (but \TeX{} takes more time producing it).

In the fourth example the \textbf{mathrm}{\textbf{bm}{g}} is essentially equivalent to \textbf{mathrm} \mbox{\textbf{boldmath}$g$}. Currently math alphabet settings are not passed down to ‘nested’ math lists, and so in this example, the \textbf{mathrm} has no effect, and a bold math italic g is obtained.

Similarly the last example is equivalent to \textbf{mbox}{\textbf{boldmath}$\textbf{mathrm}{g}$} and so in this case, one obtains a bold roman g.

### 3.2 Delimiters

\TeX{} can treat character tokens in two\footnote{Well more than two really.} ways. If there is a preceding \textbf{left} or \textbf{right} it can treat them as a delimiter, otherwise it can treat them as a standard character. For example \textbf{left}<\textbf{right>} produces ⟨⟩, which is totally different from <>, which produces <>.

\TeX{} can only do this for character tokens. Commands such as \textbf{langle} do not act in this way. This means that \textbf{bm} has to decide whether to treat a character as a delimiter or not. The rule it uses is, it makes a delimiter command for a character if the previous token in the argument was \textbf{left} or \textbf{right}. So \textbf{left}\textbf{bm}{<} does not work, but \textbf{bm}{\textbf{left}<} does.

### 3.3 Command Arguments

Normally if a command takes arguments the full command, including any arguments, should be included in \textbf{bm}.

So \textbf{bm}{\overbrace{abc}} (producing \(abc\), not \textbf{bm}{\overbrace}{abc}. If you do not include all the arguments you will typically get the error message: Runaway argument?

However commands defined in terms of the \TeX{} accent and radical primitives may be used without their arguments. So \textbf{bm}{\hat{a}} produces \(\hat{a}\), a bold accent over a non-bold a (compare \(\hat{a}\)) whereas \textbf{bm}{\hat{a}} makes both the a and the accent bold, \(\hat{a}\). Similarly, although the \TeX{} command \textbf{sqrt} must be used with its arguments, \textbf{sqrtsign} may be used as in \textbf{bm}{\sqrtsign{abc}} to produce \(\sqrt{abc}\) rather than \(\sqrt{abc}\) or \(\sqrt{abc}\).

If you really need to make a command with arguments use bold fonts without making all of the arguments bold, you can explicitly reset the math version in the argument, eg:

\[
\sqrt{xy} \quad \textbf{bm}{\sqrt{xy}} \quad \textbf{bm}{\sqrt{\textbf{mbox}{\textbf{unboldmath}$xyz$}}} \quad \sqrt{xy}
\]
3.4 Bold fonts

This package interrogates the font allocations of the bold and heavy math versions, to determine which bold fonts are available. This means that it is best to load the package after any packages that define new symbol fonts, or (like the \texttt{mathtime} package) completely change the symbol font allocations.

If no bold font appears to be available for a particular symbol, \texttt{bm} will use ‘poor man’s bold’, which will overprint the same character in slightly offset positions to give an appearance of boldness.

In the standard Computer Modern font set, there is no bold ‘large symbols’ font. In the ‘mathptm’ and (standard) mathtime font sets there are no bold math fonts. In the ‘mathtime plus’ font set there are suitable fonts for bold and heavy math setting, and so \texttt{bm} and \texttt{hm} work well. Similarly in the basic Lucida New Math font set there are no bold math fonts, so \texttt{bm} will use ‘poor man’s bold’. However, if the Lucida Expert set is used, then \texttt{bm} will detect, and use, the bold math fonts that are available.

As discussed above, one may set \texttt{bmmax} higher or lower than its default value of four to control the font allocation system. Finer control may be gained by explicitly declaring bold symbol fonts. Suppose you have a symbol font ‘xyz’ that is available in medium and bold weights, then you would declare this to \LaTeX via:

\begin{verbatim}
\DeclareSymbolFont{extras}{OMS}{xyz}{m}{n}
\SetSymbolFont{extras}{bold}{OMS}{xyz}{bx}{n}
\end{verbatim}

At this point the symbols will be available in the normal math version, and their bold variants in \texttt{boldmath}. If you also declare:

\begin{verbatim}
\DeclareSymbolFont{boldextras}{OMS}{xyz}{bx}{n}
\end{verbatim}

That is, declare a symbol font whose name is formed by prefixing ‘bold’ (or ‘heavy’) to an existing symbol font, then \texttt{bm} (or \texttt{hm}) will use this font directly, rather then accessing the ‘extras’ symbol font via \texttt{boldmath}.

3.5 Strange failures

In order to get the correct spacing, \texttt{bm} has to ‘investigate’ the definition of the commands in its argument. It is possible that some strange constructions could ‘confuse’ this investigation. If this happens then \LaTeX will almost certainly stop with a strange error. This should not happen with any of the math symbols defined in the base \LaTeX or AMS distributions, or any commands defined in terms of those symbols using normal \LaTeX math constructs. However if some command does fail to work inside \texttt{bm} you should always be able to surround it with an extra set of braces \texttt{\bm{\{\cmd\}}} rather than \texttt{\bm{\cmd}}. \texttt{bm} will not then attempt to set the correct spacing, so you may need to set it explicitly, for instance, for a relation, \texttt{\bm{\mathrel{\cmd}}}.

3.6 AMS package \texttt{amsbsy}

The \texttt{bm} command shares some functionality with the \texttt{boldsymbol} command from the AMS \LaTeX collection. To aid in moving documents between these two packages, this package defines \texttt{boldsymbol} and \texttt{heavysymbol} as alternative names for \texttt{bm} and \texttt{hm}.
4 Package Options

4.1 Logging level

As described above, the bm package has to interrogate the font setup to try to find matching bold fonts for each font used in the normal math version. This can fail in various ways as there may be no bold font or a bold font may be found but no room is available to allocate it. The options warn, info and silent control whether messages that bm produces are sent to the terminal, or just to the log file (the default) or suppressed.

4.2 Poor Man’s Bold

As discussed above, by default, if no real bold font is available, bm will use “poor man’s bold”. That is, over-printing the character with slight offsets. Since version 1.2e, the package now warns if a font is set up to use this over-printing and the package option nopbm is available which prevents its use in which case \bm will use the non-bold for characters from the affected font.

5 Implementation

Options to use or not use poor man’s bold (over-printing) and level of warning messages.

\begin{verbatim}
\DeclareOption{nopmb}{\let\bm@pmb@\@firstofone}
\DeclareOption{warn}{\def\bm@info{\PackageWarningNoLine{bm}}}
\DeclareOption{info}{\def\bm@info#1{\PackageInfo{bm}{#1\@gobble}}}
\DeclareOption{silent}{\let\bm@info\@gobble}
\ExecuteOptions{info}
\ProcessOptions\relax
\end{verbatim}

The commands \bm and \hm work by defining a number of additional symbol fonts corresponding to the standard ones ‘operators’, ‘letters’, ‘symbols’, and ‘largesymbols’. The names for these symbols fonts are produced by prefixing the usual name with ‘bold’ or ‘heavy’.

For maximum flexibility we get the font definitions by looking in the corresponding math versions, i.e., into \mv@bold and if defined into \mv@heavy.

\begin{verbatim}
\bm@table \bm@boldtable \bm@heavytable
\end{verbatim}

The table, \bm@table, (which is locally \let to either the bold or heavy version) defines, for each \langle math group \rangle \langle fam \rangle, the ‘offset’ to the bold version of the specified symbol font. If there is no bold symbol font defined, the offset will be set to zero if there is a bold font assigned to this slot in the bold math version, or \(-1\) if the font in the bold math version is the same as the one in the normal math version. In this case a ‘poor man’s bold’ system of overprinting is used to achieve boldness where this is possible.

The settings are made at the time this package is read, and so it is best to load this package late, after any font loading packages have been loaded. Symbol fonts loaded after this package will get the offset of zero, so they will still be made bold by \bm as long as an appropriate font is declared for the bold math version.
\texttt{\bm@boldtable} and \texttt{\bm@heavytable} are set up using very similar code, which is temporarily defined to \\texttt{\bm}, to save wasting a csname. Similarly \texttt{\bm@pmb}... (which will be defined later) are used as scratch macros. (This csname saving no longer used, setup command is \texttt{\bm@setup}, not \texttt{\bm}.)

The general plan. Run through the fonts allocated to the normal math version. Ignore \texttt{⟨math alphabet⟩} allocations\footnote{For now?} but for each math symbol font, look in the math version specified by \texttt{#1} (bold or heavy). If the font there is different, then allocate a new symbol font in the normal math version to access that bold font and place the numerical difference between the allocations of the bold and normal font into the table being built (\texttt{\bm@boldtable}, if \texttt{#1} is bold). If the symbol allocation is already greater than \texttt{\bmmax} do not allocate a new symbol font, but rather set the offset in the table to zero. \bm will detect this, and use \texttt{\boldmath} on its argument in this case, so the bold font will be accessed but more slowly than using a direct access to a bold font allocated into the normal math version. If the font allocated in the bold math version is the same as the font in the normal math version, set the offset to \texttt{-1}, which is a flag value that causes \bm to use ‘poor man’s bold’ overprinting three copies of the symbol, offset slightly to give an appearance of boldness.

Fonts containing delimiters and math accents must be allocated into the normal math version if they are to be used with \bm. (In these cases \bm will produce the normal weight symbol, rather than using \texttt{\boldmath} or poor man’s bold.)

\begin{verbatim}
def\bm@setup#1#2{% This code can not work inside a group, as that would affect any symbol font allocations, so instead use some scratch macros to save and restore the definitions of commands we need to change locally.
\let\bm@install@mathalphabet\install@mathalphabet 
\let\bm@getanddefine@fonts\getanddefine@fonts 
\let\bm@or\or 
\edef\bm@general{\f@encoding/\f@family/\f@series/\f@shape/\f@size} 
\#2 specifies the maximum number of fonts to allocate (either \texttt{\bmmax} or \texttt{\hmmax}). First check against \texttt{\count18} that there are that many slots left, and if not reduce accordingly. Put the resulting value in \texttt{\@tempcnta}.
\@tempcnta#2% 
\count@-\count18% 
\advance\count@-\@tempcnta 
\ifnum\count0<\z% 
\advance\@tempcnta\count0 
\fi
Make \texttt{\or} non-expandable, so we can build an \texttt{\ifcase} bit-by-bit in a sequence of \texttt{\edefs}.
\let\or\relax 
Initialise the table (to \texttt{\@gobble} to remove the first \texttt{\or}).
\expandafter\let\csname cname bm@\#1table\endcsname\@gobble
Helper macro that adds the next entry to the table being built.
\def\bm@define##1{% 
\expandafter\xdef\csname bm@\#1table\endcsname{%
\par}
}
\end{verbatim}
Each symbol font is recorded in the math version list by a sequence such as:
\getanddefine@fonts \symsymbols \OMS/cmsy/m/n
Where the first argument is a chardef token carrying the number allocated (to
symbols, in this example), and the second argument is a csname whose name
denotes the font used. So locally redefine \getanddefine@fonts to compare #2
with the name in the appropriate slot in the bold math version.
\def\getanddefine@fonts##1##2{%
  \def\@tempa{##2}%
  \def\@tempb####1##1####2####3\@nil{\def\@tempb{####2}}%
  \expandafter\expandafter\expandafter
  \@tempb\csname mv@#1\endcsname\@nil

Now \@tempa and \@tempb contain the names of the fonts allocated to this
slot in the two math versions.
\ifx\@tempa\@tempb
  If they are the same, set this offset to \texttt{-1}, as a flag to use poor man's bold.
  \bm@define\m@ne
  \bm@info{No \texttt{#1} for \texttt{\string##2}}%
  \ifx\bm@pmb@\@firstofone\else, using \texttt{\string\pmb}\fi%
\else
  Else make a new name by adjoining \texttt{#1} to the name of the symbol font, eg,
  \symsymbols to match \symsymbols. If that font has already been allo-
cated, or if \@tempcnta is positive so we can allocate a new slot for this font, then
the table will be set with the offset between the two fonts. Otherwise set the offset
to zero (so \texttt{\boldmath} will be used to access the font).
  \edef\@tempa{sym\texttt{#1}\expandafter\@gobblefour\string##1}%
  \ifnum\@tempcnta<%
    \expandafter\ifx\csname\@tempa\endcsname\relax
    \z@
  \else
    \m@ne
  \fi
  \unless \@tempcnta
    \bm@define\z@
  \else
  \fi

If the font is not yet allocated, allocate it now, using an internal hack into
\DeclareMathSymbolFont.
However before allocating it look in the bold math version to see if it is the
same, and if so use that. For example with Mathtime the ‘operators’ font in the
‘heavy’ math version is different from that in ‘normal’, but it is the same as the
font in ‘bold’ (Times bold). So rather than allocate \symheavyoperators just set
it equal to \symoperators.
\edef\@tempa{\expandafter\@gobblefour\string\texttt{\texttt{#1}}}%
\expandafter\ifx\csname\@tempa\endcsname\relax
  \begingroup
    \escapechar\m@ne
    \edef\@tempb{\endgroup
      \noexpand\split@name
      \expandafter\string\@tempb}%%
  \@tempb/%\@nil
\endgroup

7
If no font has been allocated for \texttt{bm} yet, then allocate it now.

\expandafter\new@mathgroup\csname\@tempa\endcsname
\expandafter\new@symbolfont\csname\@tempa\endcsname
\f@encoding\f@family\f@series\f@shape

Reduce by one the number of fonts we can still allocate.

\advance@tempcnta\m@ne

Else do a similar look into the bold mathgroup. Use \texttt{\textbackslash bm@expand} as a scratch macro to save on string space.

\def\bm@expand####1##1####2####3\@nil{\def\bm@expand{####2}}%
\expandafter\expandafter\expandafter
\bm@expand\csname mv@bold\endcsname\@nil
\ifx\bm@expand\@tempb
If the font just found (in heavy) is the same as the font in bold use the slot (in normal) previously allocated for the bold font. (That clear?)

\expandafter\let\csname\@tempa\expandafter\endcsname\csname symbold\expandafter\@gobblefour\string##1\endcsname

Otherwise allocate a new slot for it.

\expandafter\new@mathgroup\csname\@tempa\endcsname
\expandafter\new@symbolfont\csname\@tempa\endcsname
\f@encoding\f@family\f@series\f@shape
\advance@tempcnta\m@ne
\fi
\fi
\else

If the font has been allocated already, use the existing allocation.

\bm@info
\{Symbol font \@tempa\space already defined.\MessageBreak
Not overwriting it\}\%
\fi

Whether the font has just been allocated, or whether it was previously allocated, compute the offset and add it to the table.

\count@\csname\@tempa\endcsname
\advance@count@\m@ne
\bm@define{\the@count@\relax}%
\fi
\fi}

The math version list also contains information about math alphabet commands, but we want to ignore those here, so …
Having set up the local definitions, execute the list for the normal math version.

\mv@normal

So now the offsets are all entered into the table, separated by or. Finish off the definition by making this an ifcase. Add a default value of zero, so that any symbol fonts declared later will also work, as long as a bold version is assigned to the bold math version.

\expandafter\xdef\csname bm@#1table\endcsname{%
  \noexpand@ifcase\@tempcnta
    \csname bm@#1table\endcsname
  \noexpand\else
    \z@
  \noexpand\fi}%

Put things back as they were.

\expandafter\split@name\bm@general\@nil
\let\install@mathalphabet\bm@install@mathalphabet
\let\getanddefine@fonts\bm@getanddefine@fonts
\let\or\bm@or

\bm@setup{bold}\bmmax

\mathbf As the bold font has been defined as a symbol font, make \mathbf access that rather than have it allocate a new math group for the same font. (Just in case there were no free slots wrap this in an extra test.)

\@ifundefined{symboldoperators}
  {}
  {\DeclareSymbolFontAlphabet{mathbf}{boldoperators}}
\fi
\texttt{\textbackslash hmax} Same for heavy, but default to three this time (enough for mathtime plus, as no heavy operators font).

\begin{verbatim}
111 \ifx\hmax\@undefined
112 \chardef\hmax=3
113 \fi

   Similarly if there is a heavy math version, set up \texttt{\textbackslash bm@heavytable}. (If there is no heavy math version, do nothing here, as \texttt{\textbackslash h\textbackslash m} will be set to \texttt{\textbackslash bm} later, once that is defined.)

114 \ifx\mv@heavy\@undefined
115 \else
116 \bm@setup{heavy}\hmax
117 \fi

\texttt{\textbackslash bm@general} \texttt{\textbackslash bm} is pretty much \texttt{\textbackslash bmdefine}\texttt{/bm@command} followed by executing \texttt{\textbackslash bm@command}. It would in principle be possible to execute the emboldened tokens directly, rather than building up a macro first, but (as I learned the hard way) it’s difficult to do this in the midst of all these nested \texttt{\textbackslash if} constructs. First extract the central bit of code for \texttt{\textbackslash h\textbackslash m} \texttt{\textbackslash bm} \texttt{\textbackslash bmdefine} and \texttt{\textbackslash bmdefine}. Note that in the case of the inline versions they take an argument and brace it, rather than relying on \texttt{\textbackslash bm@general} to pick up the argument. This makes the code robust with respect to premature expansion.

118 \begingroup
119 \catcode\'\textasciitilde=\active
120 \catcode\textasciitilde=\active
121 \@firstofone\endgroup
122 \def\bm@general#1#2#3#4#5{%
123 \begingroup
First locally disable \texttt{\textbackslash bm} and \texttt{\textbackslash h\textbackslash m}, as they would mess things up terribly, and the original Spivak versions used the syntax \texttt{\textbackslash bmdefine}{\textbackslash balpha}{\textbackslash bm}{\textbackslash alpha}.

124 \let\bm\@firstofone
125 \let\h\@firstofone

183  \let\sqrt@\copy
184  \let\sqrt@@\copy
185  \let\sqrt@@@\copy
186  \global\let\bm@first\@empty
\end{verbatim}

For AMS version of \texttt{\sqrt}: don’t expand, just wrap it in a brace group so that it can be made bold in a safe but slow way. Do the same for internal accent command.

\end{verbatim}

\section*{AMS}

\begin{verbatim}
187  \let\sqrt\relax
188  \let\sqrt@\copy
189  \let\sqrt@@\copy
1810 \let\sqrt@@@\copy
1811 \global\let\bm@first\@empty
\end{verbatim}
\end{verbatim}
We have to ensure that the math alphabets have definitions that correspond the "bold" math version we are going to switch to. As these definitions are globally assigned when a math version is changed it is likely that right now we have those of the normal math version active. Argument \#3 holds either \mv@bold or \mv@heavy and we execute that after redefining \install@mathalphabet and \getanddefine@fonts suitably. The definitions are reverted back to their original the moment the scanning is done.

\let\install@mathalphabet\def
\let\getanddefine@fonts\@gobbletwo

The last redefinition just makes \mathit type commands re-insert themselves (more or less) as if they are allowed to expand they die horribly if the expansions are put into \mathchoice and so executed more than once.

\def\select@group##1##2##3##4{{%
  \protect##1{##4}}}%
\def\use@mathgroup##1##2##3{{%
  \protect\use@mathgroup##1{##2}{##3}}}%

So now start looking at the argument.

Finally outside the group either execute \bm@command (for \bm) or save its definition (for \bmdefine).

End of the \@firstofone above, and the scope of the active '.

\bm Set up the bold (rather than heavy) version, and run \bm@command right at the end, to execute the emboldened argument. The argument is grabbed by the top level function, and explicitly braced, so that \bm works even if the braces are omitted round its argument in a 'moving argument'.

\def\DeclareBoldMathCommand\@testopt\bm@declare{bold}
\def\bm@declare[#1]#2{\expandafter\bm@general\csname #1math\expandafter\endcsname\csname bm@#1table\expandafter\endcsname\csname mv@#1\endcsname\bm@define#2}}

\bmdefine Shorthand for \DeclareBoldMathCommand[bold].
\bm is empty within the definition, so that either \bmdefine\balpha{\bm\alpha} or \bmdefine\balpha{\alpha}
may be used. (The former just for compatibility with the original version for plain TeX.)

```
$\def\bmdefine{\DeclareBoldMathCommand[bold]}
```

\begin{quote}
\texttt{\textbackslash mdefine}
\end{quote}

Same again for \texttt{\textbackslash m}.

```
\begin{verbatim}
\ifx\mv@heavy\@undefined
If there is no heavy math version defined, let \texttt{\textbackslash m} be defined as \texttt{\bm}. Currently there is no warning given, perhaps there should be, or even an error?
\end{verbatim}
```

```
\let\hm\bm
\let\heavymath\boldmath
\let\bm@heavytable\bm@boldtable
\else
\end{verbatim}
```

Otherwise define \texttt{\textbackslash m} and \texttt{\textbackslash mdefine} in direct analogy with the above.

```
\DeclareRobustCommand\hm{\bm@general\heavymath\bm@heavytable\mv@heavy\bm@command}
```

```
\protected@edef\hm#1{\hm{#1}}
```

```
\def\hmdefine{\DeclareBoldMathCommand[heavy]}
\fi
```

\end{verbatim}

Normally speaking \texttt{\textbackslash outer} declarations should be avoided at all costs. (\LaTeX redirects all of plain TeX's allocation macros to be non-outer.) However this is one place where it seems like a good idea. If a command taking an argument is put in \texttt{\bm} without its argument, then the \texttt{\@@end} terminating token would be taken as the argument, and so the rest of the paragraph would be gobbled up and the \LaTeX would die horribly. So make the internal terminating token \texttt{\textbackslash outer}. (The actual test for termination is made against \texttt{\@@end} not \texttt{\textbackslash m@end} as this macro will be expanded by the look-ahead system.)

```
\outer\def\m@end{\@@end}
```

\begin{verbatim}
\bm@expand
\afterassignment\bm@exp@nd
\count@'a
\end{verbatim}

```
\def\bm@test{\let\bm@previous\@let@token
\futurelet\@let@token\bm@test@}
```

The need for this was noticed while testing \texttt{\textbackslash sqrt}. The definition of \texttt{\textbackslash root} inherited from plain \TeX has an anomalous space token, that is normally harmless (just wastes memory), but which killed earlier versions of this package.

```
\def\m@test{%
\let\m@previous@\let@token
\futurelet\@let@token\m@test@}
```

\footnote{The need for this was noticed while testing \texttt{\textbackslash sqrt}. The definition of \texttt{\textbackslash root} inherited from plain \TeX has an anomalous space token, that is normally harmless (just wastes memory), but which killed earlier versions of this package.}
If looking at a single token, switch to `\text@test@token`, else if looking at a `{ }` group, grab the whole group with `\text@group`. A `{}` token will take the wrong branch here (currently not trapped).

```
\def\text@test@{
  \ifx\text@token\text@group
    \text@group
  \else
    \text@test@token
  \fi}
```

If faced with a group when we are in math mode, put it in a `\textbf{boldsymbol}`-like construct and then recurse on `\text@expand`. Otherwise just use `\textbf{boldmath}`. The actual test is deferred till ‘run time’. Here and elsewhere could deal with the inner list with an inner call to `\text`, but that doesn’t seem to gain very much, and complicates the code quite a bit.

`#1` is either `\textbf{boldmath}` or `\textbf{heavymath}`. Need to add an extra set of explicit braces around `#2` as otherwise the math style commands applied in `\textbf{mathchoice}` might only apply to the first half of an `\textbf{over}` construction.

```
\def\text@group#1#2{
  \ifmmode
    \textbf{mathchoice}#1{#2}{#2}{#2}{#2}%
  \else
    \textbf{#1}#2%
  \fi}
```

If not facing a `{ }` group then test to see what we have. Basic idea: Trap `\textbf{mathchar}` tokens, character tokens, and calls to `\textbf{mathchar}`, `\textbf{mathaccent}`, etc, and change the `\textbf{math-group}` (fam) to point at the bold version. Other things just copy straight over to the command being built. (Anything inside a `\textbf{mathop}` or similar will end up being made bold as the `\textbf{mathop}` will be copied over, but its argument will be made bold by the group code above.)

```
\def\text@test@token#1{
  \let\text@next\@empty
  \ifx#1\@nil
    \text@mathchoice
  \else
    \ifx#1\textbf{mathchoice}
      \let\text@next\text@mathchoice
    \else
      \ifx#1\textbf{mathchar}
        \text@mathchar\count@
      \else
        \textbf{mathaccent}
      \fi
    \fi
  \fi
}
```

Stop here. Note that it is vital that the terminating token is non-expandable and defined, rather than the usual L\TeX\ terminators `\@nil` and `\@@`. (Worse still would be a ‘quark’ like docstrip’s `\textbf{qStop}.`)

```
\ifx\@nil\@empty
  \textbf{mathchoice}
\else
  \textbf{\textbf{mathchar}}
\fi
```

The main point: Find these expressions, and change the mathgroup.
Need to trap spaces, otherwise digits will get turned to bold mathchars.

\bmdefine

End code for \bmdefine. Define the given command name to the robust form of the accumulated code.

If \bmcommand is equal to \@gtempa then it is a macro whose expansion is a single call to \mathchar, so that can be optimised with a \mathchardef.

267 \def\bmdefine#1{% 
268 \begingroup 
269 \ifx\bmcommand\@gtempa 
270 \def\mathchar{\global\mathchardef#1}% 
271 \bmcommand 
272 \else 
Rather than simply \let#1\bmcommand, make the defined command robust.
\bmfirst is normally empty, but might be something like \DOTSI which needs to be lifted to the top level, in front of any \protect because of the lookahead mechanism used in the amsmath package.

273 \toks0\expandafter{\bmcommand} 
274 \xdef#1{\bmfirst\noexpand\bmprotect\noexpand#1\the\toks0}% 
275 \fi 
276 \endgroup}

\bmprotect

Commands defined by \bmdefine re-insert themselves if protection is enabled.

277 \def\bmprotect#1{% 
278 \ifx\protect\@typeset@protect 
279 \expandafter\@firstofone 
280 \else 
281 \protect#1\expandafter\@gobble 
282 \fi}

\bmchoice

\boldsymbol, more or less. #1 is either \boldmath or \heavymath.

283 \def\bmchoice#1#2#3#4#5{% 
284 \mathchoice{\hbox{#1$\displaystyle\m@th#2$}}% 
285 {\hbox{#1$\textstyle\m@th#3$}}% 
286 {\hbox{#1$\scriptstyle\m@th#4$}}% 
287 {\hbox{#1$\scriptscriptstyle\m@th#5$}}} 

\bm@thchoice

Action if you find a \mathchoice. Add the bold version to \bmcommand then recurse.

#1 is either \boldmath or \heavymath.

288 \def\bm@thchoice#1#2#3#4#5{% 
289 \bm@add{\bmchoice#1{#2}{#3}{#4}{#5}}} 

\bm@r@gister

Combined code for setting up \bm@r@gister with the correct register type.

290 \def\bm@r@gister#1#2{% 
291 \def\@tempa{#1\the#2}% 
292 \afterassignment\bm@r@gister#2}

\bm@r@gister

\mkern itself would transfer to \bmcommand without any special test, but any explicit dimension following would be converted to \mathchar. So trap this and grab the muskip as a muskip. This is used in \iiint. \penalty was needed for the AMS version of \colon, and so do most of the others as well.

293 \def\bm@r@gister{% 
294 \bm@xadd{\@tempa\space}}
\texttt{\textbackslash bm@mathchar} Change the family (math group) of a mathcode and then use the modified code with \texttt{\textbackslash mathchar}. If there is no suitable bold font in the current math version, use the original unmodified mathcode, but switch to \texttt{\textbackslash boldmath} (if there is a bold font there) or use ‘poor man’s bold’. Note that these other possibilities are only possible here, not for the otherwise similar code for \texttt{\textbackslash delimiter} or \texttt{\textbackslash mathaccent}, as those commands must work with fonts from the same math version.

Finally recurse down the list.

\bm@mathaccent \texttt{\mathaccent} version of \texttt{\bm mathchar}.
\def\bm@mathaccent{\bm@changefam{}\The next four lines were added in v1.0e. Without them \texttt{\bm\hat{A}} makes the accent bold using \texttt{\bm} but the group \{A\} is made bold via a \texttt{\mathchoice} construction as for any other group, as \texttt{\bm} does not attempt to parse inside brace groups. While that produces something acceptable for lower case letters, it produces \(\hat{A}\) which is not too good. The braces may simply be omitted: \texttt{\bm\{\hat A\}} would work, producing \(\hat A\), however I did not want to document such a restriction, so now modify \texttt{\bm} so that such brace groups are handled gracefully.

It would be possible to locally make mathaccents take an argument during the bm look-ahead, so the brace groups would then vanish during expansion, however if the braces may simply be omitted: \texttt{\bm\{\hat A\}} would work, producing \(\hat A\), however I did not want to document such a restriction, so now modify \texttt{\bm} so that such brace groups are handled gracefully.

So instead do the following which gets rid of \texttt{(filler)} with a redefinition of \texttt{\relax}, and just locally changes \texttt{\bm group} so that instead of doing a \texttt{\mathchoice} it simply adds \texttt{\bgroup} and \texttt{\egroup} around the tokens, and lets \texttt{\bm} modify the tokens of the ‘argument’. This means that \texttt{\bm\{\hat{A}\}} now produces

\texttt{\mathaccent 29790 \bgroup \mathchar 30017 \egroup}
The inner math list is a single mathchar, and so \TeX{} will not box it, and the math accent will correctly position, taking into account the skewchar information.

As the normal bm look-ahead is used, it is automatic that the parse will end without trying to go past \texttt{\bm\end}.

One disadvantage is that the group will mean that \texttt{\bm\previous} will not be correctly updated. However that is only used for delimiter checking, so can not matter here.

\def\bm@group##1{\endgroup\bm@test@token\bgroup##1\egroup}\
